

# STATISTICS FUNDAMENTALS

---

# STATISTICS FUNDAMENTALS

---

## LEARNING OBJECTIVES

- ▶ Use NumPy and Pandas libraries to analyze datasets using basic summary statistics: mean, median, mode, max, min, quartile, inter-quartile range, variance, standard deviation, and correlation
- ▶ Create data visualizations - including: line graphs, box plots, and histograms- to discern characteristics and trends in a dataset
- ▶ Identify a normal distribution within a dataset using summary statistics and visualization
- ▶ ID variable types and complete dummy coding by hand

---

**COURSE**

---

**PRE-WORK**

---

# PRE-WORK REVIEW

---

- ▶ Create and open an Jupyter Notebook
- ▶ Complete the Python pre-work

---

**OPENING**

---

# STATISTICS FUNDAMENTALS

# LET'S REVIEW THE DATA SCIENCE WORKFLOW

The steps:

1. Identify the problem
2. Acquire the data
3. Parse the data
4. Mine the data
5. Refine the data
6. Build a data model
7. Present the results

---

# TODAY

---

- ▶ We're going to begin to talk about step 3: Parsing the Data
- ▶ We'll begin to talk about the fundamentals of Statistics

---

## INTRODUCTION

---

# CENTRAL LIMIT THEOREM REFRESHER

---

# WE'RE GOING TO COVER SEVERAL TOPICS

---

- ▶ Mean
- ▶ Median
- ▶ Mode
- ▶ Variance
- ▶ Standard Deviation
- ▶ Quartile
- ▶ Interquartile Range
- ▶ Max
- ▶ Min
- ▶ Covariance
- ▶ Correlation

# MEAN

- ▶ The mean of a set of values is the sum of the values divided by the number of values. It is also called the average.

$$\overline{X} = \frac{\sum X}{N}$$

---

## MEAN EXAMPLE

---

- ▶ Find the mean of 19, 13, 15, 25, and 18.

---

## MEAN EXAMPLE

---

- Find the mean of 19, 13, 15, 25, and 18.

$$\frac{19 + 13 + 15 + 25 + 18}{5} = \frac{90}{5} = 18$$

# MEDIAN

- ▶ The median refers to the midpoint in a series of numbers.
- ▶ To find the median
  - ▶ Arrange the numbers in order smallest to largest.
  - ▶ If there is an odd number of values, the middle value is the median.
  - ▶ If there is an even number of values, the average of the middle two values is the median.

---

## **MEDIAN EXAMPLE**

---

- ▶ Find the median of 19, 29, 36, 15, and 20.

---

## MEDIAN EXAMPLE

---

- Find the median of 19, 29, 36, 15, and 20.

Ordered Values:

15, 19, 20, 29, 36

20 is the median

---

## MEDIAN EXAMPLE

---

- ▶ Find the median of 67, 28, 92, 37, 81, 75.

---

# MEDIAN EXAMPLE

---

► Find the median of 67, 28, 92, 37, 81, 75.

Ordered Values:

28, 37, 67, 75, 81, 92

67 and 75 are the middle values.

$$\frac{67 + 75}{2} = \frac{142}{2} = 71$$

71 is the median.

# MODE

- ▶ The mode of a set of values is the value that occurs most often.
- ▶ A set of values may have more than one mode or no mode.

---

## MODE EXAMPLE

---

- Find the mode of 15, 21, 26, 25, 21, 23, 28, and 21.

---

## MODE EXAMPLE

---

► Find the mode of 15, 21, 26, 25, 21, 23, 28, and 21.

21 is the mode because it occurs most frequently

---

## MODE EXAMPLE

---

- Find the mode of 12, 15, 18, 26, 15, 9, 12, and 27.

---

## MODE EXAMPLE

---

► Find the mode of 12, 15, 18, 26, 15, 9, 12, and 27.

12 and 15 are the modes since the both occur twice.

---

## MODE EXAMPLE

---

- Find the mode of 4, 8, 15, 21, and 23.

---

## MODE EXAMPLE

---

► Find the mode of 4, 8, 15, 21, and 23.

There is no mode since all values occur the same number of times.

---

# ACTIVITY: KNOWLEDGE CHECK

---

## EXERCISE

### ANSWER THE FOLLOWING QUESTIONS (5 minutes)

1. For the following groups of numbers, calculate the mean, median and mode by hand. Also determine the min and max.
  - a. 18, 24, 17, 21, 24, 16, 29, 18
  - b. 75, 87, 49, 68, 75, 84, 98, 92
  - c. 55, 47, 38, 66, 56, 64, 44, 39

### DELIVERABLE

Answers to the above questions

---

# QUARTILES AND INTERQUARTILE RANGE

---

- ▶ Quartiles divide a rank-ordered data set into four equal parts.
- ▶ The values that divide each part are called first, second, and third quartiles, denoted  $Q_1$ ,  $Q_2$ , and  $Q_3$ , respectively.
- ▶ The interquartile range (IQR) is  $Q_3 - Q_1$ , a measure of variability.

**CODEALONG**

---

# SUMMARY STATISTICS IN PANDAS

---

## CODEALONG: SUMMARY STATISTICS IN PANDAS

---

- ▶ Open the starter-code notebook located in **lessons/lesson-03/code/starter-code** of the class repo.

---

# CODEALONG PART 1: BASIC STATS

---

► We can use Pandas to calculate the mean, median, mode, min, and max.

Methods available include:

`.min()` - Compute minimum value

`.max()` - Compute maximum value

`.mean()` - Compute mean value

`.median()` - Compute median value

`.mode()` - Compute mode value

`.count()` - Count the number of observations

---

## CODEALONG PART 2: BOX PLOT

---

- Box plots give a nice visual of min, max, median (and mean when specified), and the quartile and interquartile range.

---

# BIAS VS. VARIANCE

---

- ▶ Error due to **bias** is calculated at the difference between the *expected prediction* of our model and the *correct value* we are trying to predict.
- ▶ Imagine creating multiple models on various datasets. **Bias** measures *how far off in general* models' predictions are from the correct value.

---

# BIAS VS. VARIANCE

---

- ▶ Error due to **variance** is taken as the variability of a model prediction for a given point.
- ▶ Imagine creating multiple models on various datasets. The **variance** is *how much the predictions for a given point vary* between different realizations of the model.

# BIAS VS. VARIANCE

---

# VARIANCE

---

- ▶ Variance ( $\sigma^2$  for population,  $s^2$  for sample) is the sum of squared distances from the sample mean
- ▶ Useful for equations, not so much for interpretation
  - ▶ Not in units of data

$$s^2 = \frac{\sum (x - \bar{x})^2}{n - 1}$$

---

# STANDARD DEVIATION

---

- ▶ Standard deviation (SD,  $\sigma$  for population,  $s$  for sample) is the square root of variance
- ▶ In the same units as data (eg. cm, weight, etc)

$$s = \sqrt{\frac{\sum (x - \bar{x})^2}{n - 1}}$$

---

# STANDARD ERROR

---

- ▶ The standard error of the mean (SEM) quantifies the precision of sample the mean.
- ▶ It is a measure of how far your sample mean is likely to be from the population mean.

$$SE_{\bar{x}} = \frac{s}{\sqrt{n}}$$

---

## CODEALONG PART 3: STANDARD DEVIATION & VARIANCE

---

► You can calculate variance and standard deviation easily in Pandas.

Methods include:

`.std()` – Compute Standard Deviation

`.var()` – Compute variance

`.describe()` – short cut that prints out count, mean, std, min, quartiles, max

---

# Covariance

---

- ▶ The covariance is a measure of linear relationship between two variables
- ▶ Closer the data line up along a straight line, larger the covariance
- ▶ Like variance, covariance is useful for equations, not so much for interpretation
  - ▶ Values can range from - inf to + inf
  - ▶ Not standardised (can't compare different combinations of variables)

$$COV(X,Y) = \frac{\sum_{i=1}^n (X_i - \bar{X})(Y_i - \bar{Y})}{n-1}$$

---

# CORRELATION

---

- ▶ Standardised version of covariance (cov / standard deviation of var 1 \* var 2)
- ▶ Values range from -1 (strong negative relationship) to +1 (strong positive relationship). A value of 0 indicates no relationship.

$$r = \frac{\sum (x - \bar{x})(y - \bar{y})}{\sqrt{\sum (x - \bar{x})^2 \sum (y - \bar{y})^2}}$$

$$\text{Correlation} = \frac{\text{Cov}(x, y)}{\sigma x * \sigma y}$$

# CORRELATION

- ▶ The correlation measures the extent of interdependence of variable quantities.
- ▶ Example correlation values

---

## CODEALONG PART 4: COVARIANCE AND CORRELATION

---

- ▶ No need to compute by hand! Covariance and correlation are easily calculated in Pandas!

Methods include:

`.cov()` - Compute Covariance

`.corr()` - Compute Correlation

---

# CONTEXT

---

- ▶ For most projects, descriptive stats will come first. These help you get to know your dataset better.
- ▶ Sometimes, descriptive stats may be all you need to answer your question.

---

## INTRODUCTION

---

# IS THIS NORMAL?

---

# THE NORMAL DISTRIBUTION

---

- ▶ A normal distribution is often a key assumption to many models (remember the start of the lesson?).
- ▶ The normal distribution depends upon the *mean* and the *standard deviation*.
- ▶ The *mean* determines the center of the distribution. The *standard deviation* determines the height and width of the distribution.

---

# THE NORMAL DISTRIBUTION

---

- ▶ Normal distributions are symmetric, bell-shaped curves.
- ▶ When the standard deviation is large, the curve is short and wide.
- ▶ When the standard deviation is small, the curve is tall and narrow.

# SKEWNESS

- ▶ Skewness is a measure of the asymmetry of the distribution of a random variable about its mean.
- ▶ Skewness can be positive or negative, or even undefined.

---

# KURTOSIS

---

- ▶ Kurtosis is a measure of whether the data are peaked or flat relative to a normal distribution.
- ▶ Datasets with high kurtosis tend to have a distinct peak near the mean, decline rather rapidly, and have heavy tails.

**DEMO**

---

# DETERMINING THE DISTRIBUTION OF YOUR DATA

---

# DETERMINING THE DISTRIBUTION OF YOUR DATA

---

- ▶ Follow along as we walk through this in an Jupyter Notebook.

---

## INTRODUCTION

---

# VARIABLE TYPES

---

# VARIABLE TYPES

---

- ▶ Numeric variables can take on a large range of non-predetermined, quantitative values. These are things such as height, income, etc.
- ▶ Categorical variables can take on a specific set of variables. These are things such as race, gender, paint colors, movie titles, etc.

---

**DEMO**

---

# DUMMY VARIABLES

---

# DUMMY VARIABLES

---

- ▶ Let's say we have the categorical variable `area`, which takes on one of the following values: `rural`, `suburban`, and `urban`.
- ▶ We need to represent these numerically for a model. So how do we code them?

---

# DUMMY VARIABLES

---

► How about 0=rural, 1=suburban, and 2=urban?

---

# DUMMY VARIABLES

---

- ▶ But this implies an ordered relationship - is urban twice suburban?  
That doesn't make sense.
- ▶ However, we can represent this information by converting the one area variable into two new variables:

area\_urban and area\_suburban.

---

# DUMMY VARIABLES

---

- ▶ We'll draw out how categorical variables can be represented without implying order.
- ▶ First, let's choose a reference category. This will be our “base” category.
- ▶ It's often good to choose the category with the largest sample size and a criteria that will help model interpretation. If we are testing for a disease, the reference category would be people without the disease.

---

# DUMMY VARIABLES

---

- ▶ Step 1: Select a reference category. We'll choose `rural` as our reference category.
- ▶ Step 2: Convert the values `urban`, `suburban`, and `urban` into a numeric representation that does not imply order.
- ▶ Step 3: Create two new variables: `area_urban` and `area_suburban`.

---

# DUMMY VARIABLES

---

- ▶ Why do we need only two dummy variables?

rural	urban	suburban
-------	-------	----------

- ▶ We can derive all of the possible values from these two. If an area isn't urban or suburban, we know it must be rural.
- ▶ In general, if you have a categorical feature with  $k$  categories, you need to create  $k-1$  dummy variable to represent all of the information.

---

# DUMMY VARIABLES

---

► Let’s see our dummy variables.

	area_urban	area_suburban
rural	0	0
suburban	0	1
urban	1	0

► As mentioned before, if we know  $\text{area\_urban}=0$  and  $\text{area\_suburban}=0$ , then the area must be rural.

---

# DUMMY VARIABLES

---

- ▶ We can do this for a gender variable with two categories: male and female.
- ▶ How many dummy variables need to be created?

---

# DUMMY VARIABLES

---

▶ # of categories - 1 = 2 - 1 = 1

---

# DUMMY VARIABLES

---

- ▶ We will make `female` our reference category. Thus, `female=0` and `male=1`.

	<b>gender_male</b>
<code>female</code>	0
<code>male</code>	1

- ▶ This can be done in Pandas with the `get_dummies` method.

---

**CONCLUSION**

---

**TOPIC REVIEW**

---

# REVIEW

---

- ▶ We talked about several different types of summary statistics, what are they?
- ▶ We covered several different types of visualizations; which ones?
- ▶ We talked about the normal distribution.
- ▶ Any other questions?
